BACKGROUND
Aortobifemoral bypass grafting has been the traditional treatment for extensive aorto-iliac occlusive disease (AIOD). Less invasive alternative to open surgery was described for the treatment of severe AIOD (1)(2).

Endovascular procedures for AIOD seem to be associated with superior short-term clinical and economic outcomes compared with open surgery (3) and a lower risk for complications and mortality (4) allowing a primary endovascular approach to be considered as the first line of treatment for focal aortic lesions (5).

Covered stents performed better for TASC C and D lesions than bare stents in longer-term patency and clinical outcome (6).

Recently the Covered Endovascular Reconstruction of Aortic Bifurcation or CERAB-technique (7) appeared to be a safe and feasible alternative to open surgical reconstruction of the aortic bifurcation in complex occlusive disease (8).

OBJECTIVE
Feasibility and safety of an endovascular therapeutic approach was prospectively assessed in consecutive patients with severe AIOD.

MATERIAL AND METHODS
Between January 2013 and August 2015, 74 patients (46 male, 28 female) suffering from severe claudication (75.7%) or critical limb ischemia (24.3%) due to obstructive lesions at the level of the aortic bifurcation were treated with endovascular techniques. 11 patients also presented with an infrarenal aortic aneurysm (14.9%). The median age was 63 years (range 44-85 years). Lesion morphology was evaluated by CT angiography. 23 TASC-II C lesions, and 51 TASC-II D lesions were treated. Follow up was a median 7.4 months (range 23.9 months) and consisted of clinical examination and duplex ultrasound examination.

TECHNIQUE
Patients are prepared for open surgery. A bilateral femoral approach is performed in case of a combined hybrid procedure. In the other cases a percutaneous approach is the method of choice. A brachial or subclavian approach is routinely performed to allow an antegrade recanalization or chimney procedure.

RESULTS
Technical success was obtained in all patients. In three cases lesions could not be recanalized on one side and the patients were treated with an aorto-monolical device and crossover bypass.

Primary patency was 95.9% at 1 year, while assisted primary patency was 100% at 1 year. 3 patients had an occlusion of one iliac artery treated in 2 cases with Rotarex and PTA. 1 patient had a crossover bypass during follow-up.

There was a 30 day mortality of 5/74 patients (6.8%) due to 1 myocardial infarction, 2 respiratory failures, 1 inhalation pneumonia and 1 mesenteric ischemia for a patient treated with an acute Leriche syndrome. Survival rate at 3 months was 93%, at 2 years 91.2%. 26 stentgrafts were used (1 fenestrated stentgraft and 7 chimney grafts).

201 stents (161 covered stents) were used (2.7 / patient).

Three patients had a minor amputation, no patient had a major amputation. 10 patients had a postoperative groin hematoma, one patient had an intraoperative disruption of an iliac artery treated with a covered stent.

CONCLUSION
Endovascular technique appears to be a safe and feasible alternative to open surgical reconstruction of the aortic bifurcation in complex occlusive disease. There is a need for dedicated stentgrafts for occlusive disease because the radial force of conventional stentgrafts does not allow to treat the lesions without the help of BX stents.
